(54) Flexible polyurethane foam for sound insulation purposes, process for the production and use thereof

(57) A flexible polyurethane foam for sound insulation purposes has viscoelastic properties in the temperature range of -20 to +80°C and a loss factor of at least 0.3, in the case of a density of less than 90 kg/m³ and a modulus of elasticity of less than 106N/m². The foam is obtained by reacting a polyisocyanate with a polyol, in which at least one component has an OH-number of 180 to 400. The foam is particularly suitable for airborne sound absorption and insulation, as well as for structure-borne sound insulation.

FIG. 1

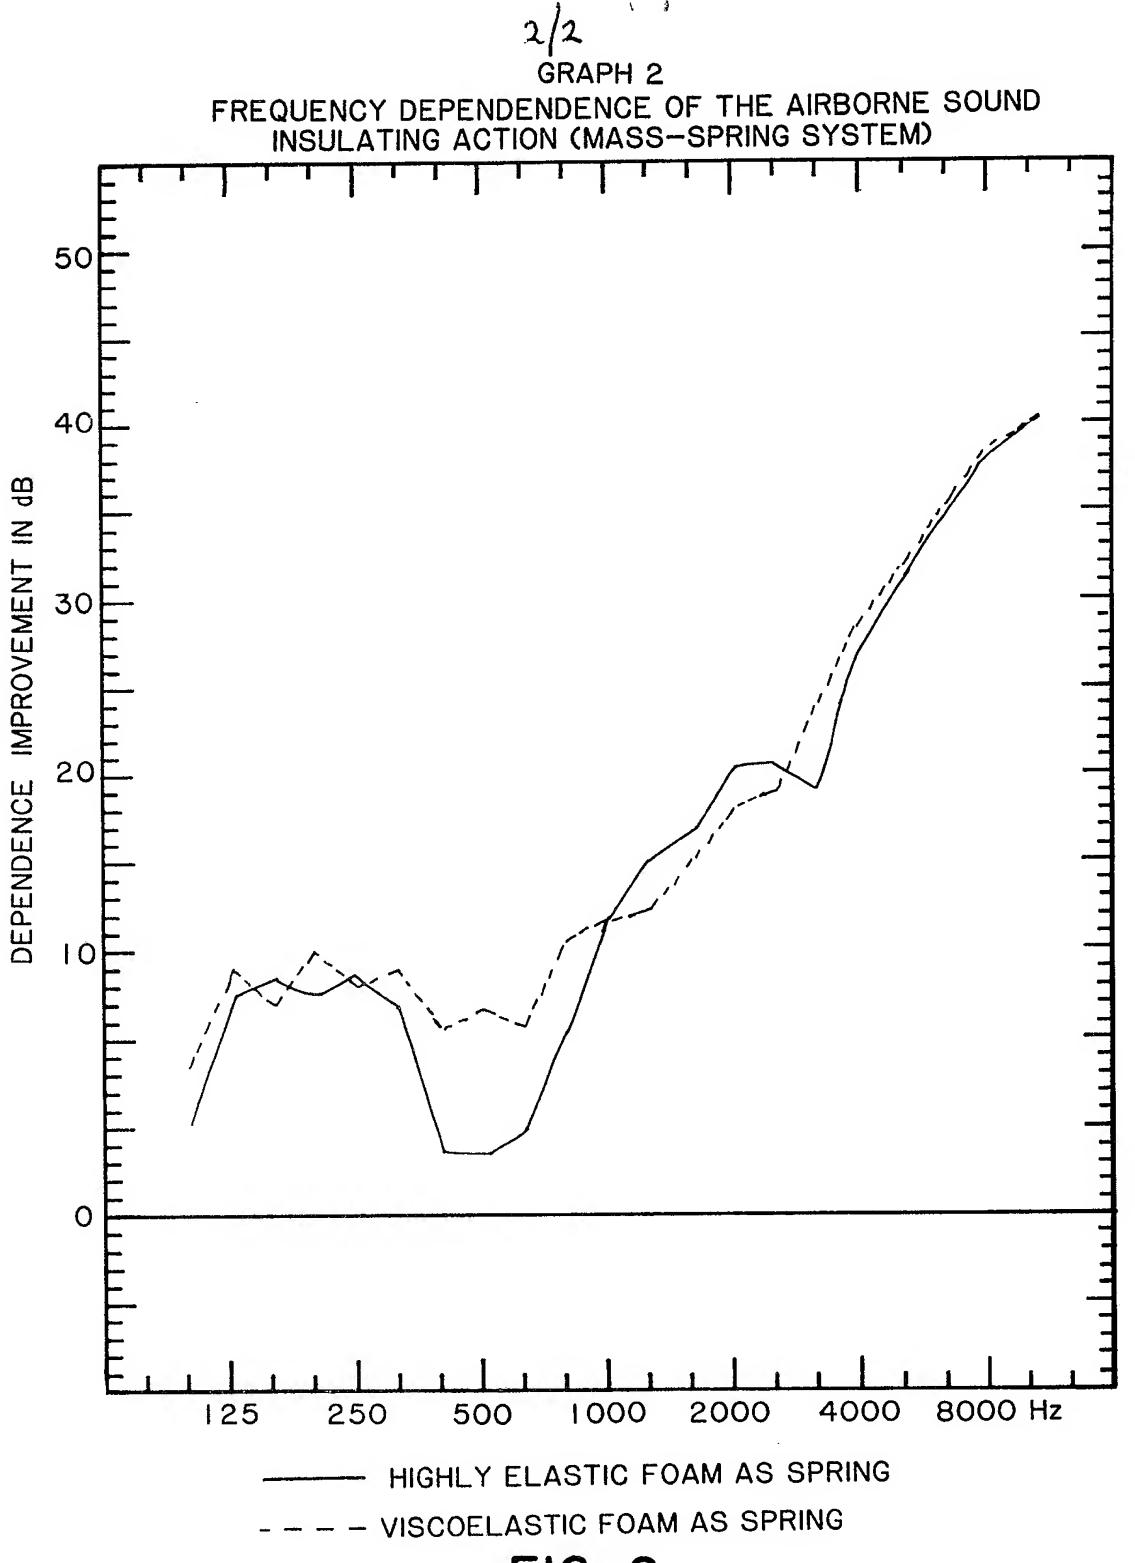

FIG. 2

SPECIFICATION

5	Flexible polyurethane foam for sound insulation purposes, process for the production and use thereof	5
S	Polyurethane foams have already been used in many forms for sound insulation purposes. Thus, for a long time now, mats have been used for lining the walls of motor vehicle bodies and which for obtaining a good sound insulation are made from highly filled polyurethane foam having a	
10	bulk density of 0.5 to 1.25 kg/1, cf DE-AS 1,923,161 and DE-OS 2,835,329. However, such materials have a relatively high modulus of elasticity or a low loss factor and are consequently too rigid to form the spring of a mass-spring system. In addition, in the car industry, the trend is increasingly towards lighter weight materials for sound insulation systems in order to achieve a weight saving. This demand cannot be met by the high bulk density of the	10
15	It is also known to use open-cell polyurethane foams for airborne sound absorption purposes. However, as such foams easily absorb dirt and moistures in the same way as a sponge, it is generally necessary to apply a covering layer to the absorber foam, which clearly impairs the acoustic properties.	15
20	Finally, it is known to improve sound insulation by the double-wall effect. For this purpose, a flexible plastic layer (mass) is placed on the wall to be insulated (e.g. the vehicle body) at a distance of approximately 10 to 30mm. The space between the body and the plastic layer is filled with a soft polyurethane foam (spring). Such mass—spring systems advantageously lead to better sound inslulation at higher frequencies, but suffer from the disadvantage of resonance (intrusions) at lower frequencies.	20
25		25
30	moulded articles, optionally also as back-foaming, in conjunction with other materials and which leads to both an improvement in the airborne sound absorption and, when used as the spring in the mass-spring systems, leads to an improvement to the airborne sound insulation in the resonant frequency range. In addition, when used with or without a septum, the foam material	30
35	also leads to an improvement of the structure-borne sound insulation. According to the invention, it has been found that this can be achieved by producing a flexible polyurethane foam, which has viscoelastic properties in the practically important temperature range of -20 to +80°C. Thus, the invention provides a flexible polyurethane foam for sound insulation purposes,	35
40	which is largely filler-free and has a density of less than 90 kg/m ³ and a modulus of elasticity of less than 10^6 N/m ² , has a loss factor of at least 0.3 and has viscoelastic properties at temperatures of from -20 to $+80^{\circ}$ C.	40
45	Although the viscoelastyic foam of the invention will not normally contain any filler small amounts of filler can be tolerated. Thus, the foam according to the invention possesses a very low bulk density and a very low modulus of elasticity, the latter preferably being about 5×10^5 N/m². The acoustic loss factor is at least 0.3 and is preferably about 0.5. In addition, the material has good thermal stability, the permanent deformation being less than 5%, following 70% deformation at 80°C for 22 hours.	45
50	When manufacturing and processing the flexible polyurethane foam according to the invention, a polyisocyanate is reacted with a polyol mixture, in which at least one component has a OH-number of from 180 to 400, then by means of the RIM-process shaped foam articles, optionally in conjunction with other materials, are produced from the viscoelastic polyurethane. The RIM process (Reaction Injection Moulding) involves rapid injection of metered liquid streams of polyol and an isocyanate into a mold. There may also be other materials e.g. a heavy	50
55	plastic film or a carpet material present in the mold when the foam is formed. The necessary demoulding times are less than 3 minutes, so that it is economically possible to manufacture large quantities. Propylene oxide-based polyether triols are particularly suitable as polyols. However as the	55
60	polyol component with a OH-number of from 180 to 400, it is also possible to use linear and branched polyester and polyols, linear and branched products of ring-opening polymerizations of tetrahydrofuran and polyethylene glycols. Preferably, the OH-number of the polyol does not exceed 350, i.e. is between 180 and 350. The proportion of the polyol component with a OH-number of 180 to 400 and preferably 180 to 350 in the polyol mixture (first component) is at least 15, but preferably 25 to 50% by weight.	60
65	The polyisocyanates can be formed by both aliphatic and aromatic isocyanates. Preference is mainly given to crude dimethyl methane diisocyanate, isomers of tolylene diisocyanates,	65

55

	optionally mixtures of t	the two, together	with DMI-prepolymers having a low molecular weight			
	(NCO-content between 20 and 28% by weight).					
		• •	rethane foam according to the invention with the			
5	aforementioned properties follows standard prior art methods for cold moulding foams (cf e.g. George Woods "Flexible Polyurethane Foams", Chemistry and Technology, 1982, particularly pp.47 to 71 and 158 to 180). For this purpose, the polyol mixture, including the standard additives such as blowing agent, cell stabilizers, catalysts, pigments, etc (first component) is reacted with the polyisocyanate (second component). It must be ensured that the NCO-characteristic or index does not exceed the value 105.					
10				10		
10	suitable for use in sound insulation. The material according to the invention can be advantage- ously used for airborne sound absorption, because it has a sufficiently open-cell nature. Cell opening takes place at the time of production, so that there is no need to rework the foam.					
15	When using the foam according to the invention, the airborne sound insulation with the aid of mats-spring systems is also clearly improved in the low frequency range (resonant frequencies As a result of its viscoelastic properties, when the material is applied to structure-borne soundemitting oscillating sheets, the material contributes to the damping thereof, when used with own without a septum.
